

This is the most important heading on the page

This is another heading

Hello! Here is a paragraph of text. It can be short or long, and it can [contain links](#). You can for example mark some words as **important** in one way or *another*.

Lists

Here is a list of things I like in order of preference:

1. Kittens
2. Space
3. Lie-ins
4. Playing games

And here is a list of things I often do, but they are not in a particular order:

- Do my homework
- Read my favourite book
- Visit a friend
- Go for walks
- Watch films

Grouping things

I have put this particular paragraph in a box. `<div>` is a box that you can put other things into. It comes in useful when you want to group things together.

You can use `classes` to annotate the elements in code. They can help you distinguish between the same elements that you might use for different things. `classes` are not visible, but later you will learn how to use them to change appearance of things on the page.

You can have many elements with the same `class`.

You can also use `id` for a similar purpose: use it when you want to mark out a specific element

You can only have *one* element with a specific `id` though, but as a bonus you can [link to that element](#) within the page.

Images

Ooh, see how we introduced another tag? `` (the image tag) lets you put in some pictures.
